Table 5.1 Comparing handler parameters and `PageModel` properties

	Handler parameter	`PageModel` property
HTTP method	Supports binding during both `GET` and `POST` requests by default	Requires opt-in using the `BindProperty` attribute and additional opt-in for `GET` request binding
Scope	Only accessible within the handler they belong to	Accessible throughout the `PageModel` class and in the associated Razor page via its `Model` property
Validation	Cannot participate in client-side validation	Participates in both client-side and server-side validation

The last entry in the preceding table touches on a topic we have yet to explore: input validation. That is what we will look at next.

5.3 Validating user input in Razor Pages

When you allow users to provide values that you then process, you need to ensure the incoming values are of the expected data type, they are within the permitted range, and required values are present. This process is known as *input validation*.

The term *user input* covers any value the user has control over. Values provided via forms constitute the bulk of user input, but user input also comes in the form of values provided in URLs and cookies. The default position should be that all user input is to be considered untrusted and should be validated against business rules. In this section, you will concentrate on validating form values.
