Validation library, developed by Microsoft, which builds on the popular and well-tested jQuery Validation library.

The future of jQuery-based validation

There is an open work item in the ASP.NET Core Github repo (https://github.com/dotnet/aspnetcore/issues/8573) that discusses the potential future removal of jQuery as a dependency in the project templates. Clearly this would impact future client-side validation approaches. It appears to be a major undertaking if it is to happen, but it is worth keeping an eye on to see how the issue unfolds. Obviously, if jQuery is removed from future templates, that will have no impact on applications that have been developed prior to that point.

You must include jQuery Unobtrusive Validation scripts within the page containing the form for client-side validation to work. This is most easily accomplished by the inclusion of the _ValidationScriptsPartial.cshtml file (located in the Shared folder) within the page, using the partial tag helper you saw in chapter 3:

```
@section scripts{
  <partial name="_ValidationScriptsPartial" />
}
```

You must also ensure jQuery is available to the page. It is included in the default layout page, so as long as your form is in a page that references the layout, there is nothing else you need to do.

Client-side validation depends on custom HTML5 `data-val-*` attributes emitted by tag helpers. To see how that works, in listing 5.22, you revert the Create page in the CountryManager back to inserting one country at a time, with one difference: the addition of validation attributes on the `InputModel` properties.
