Listing 5.22 Adding validation attributes to the input model properties

```
public class CreateModel : PageModel
{
    [BindProperty]
    public InputModel Input { get; set; }
    public Country Country { get; set; }

    public void OnPost()
    {
        Country = new Country{
            CountryCode = Input.CountryCode,
            CountryName = Input.CountryName
        };
    }

    public class InputModel
    {
        [Required]
        public string CountryName { get; set; }
        [Required, StringLength(2, MinimumLength = 2)]    ❶
        public string CountryCode { get; set; }
    }
}
```

❶ Both properties are marked as required. The CountryCode must be 2 characters in length.

The attributes have been applied to the properties. Both properties have the `Required` attribute, which means the user has to provide a value. In addition, you are validating the `CountryCode` value for length. The value provided by the user must be two characters long. You have used the `StringLength` attribute for this, setting both the maximum and minimum values to `2`. You can apply multiple attributes in one set of square brackets, separated by commas, or you can apply them individually if you prefer.

The revised form uses input tag helpers along with validation tag helpers. The validation tag helpers target the `span` element and are responsible for rendering validation error messages for the property specified by its `validation-for` attribute.
