The span automatically has a CSS class of `field-validation-error` applied to it when an error occurs. You could use this class to apply styles to the rendered error message, but you have already used the Bootstrap `text-danger` class to apply a red color to the output.

All validation attributes have an `ErrorMessage` property that enables you to set your own custom error message instead of relying on the default error messages set by the attribute authors. The following listing illustrates how you could change the error message for the country code field.

Listing 5.27 Setting a custom error message through the `ErrorMessage` property

```
[Required, StringLength(2, MinimumLength = 2,
    ErrorMessage = "You must provide a valid two character ISO 3166-1 code")]
public string CountryCode { get; set; }
```

You can opt a property out of validation by adding the `ValidationNever` attribute to it. This attribute belongs to a different namespace, so you will need to add a using statement:

```
@using Microsoft.AspNetCore.Mvc.ModelBinding.Validation
```

The `data-val` validation attributes are not rendered by a tag helper with a property that has this attribute applied to it.

The validation tag helper is responsible for outputting validation error messages for individual properties. You may also want to present the user with a summary of validation errors or a general validation error message, which you can use the validation summary tag for. It targets a `div` element and allows you to control the level of detail included in the message by
