passing a value to the `validation-summary` attribute. Acceptable values are `None`, `ModelOnly`, and `All`:

```
<div asp-validation-summary="All" class="text-danger">There are errors</div>
```

When you pass `None`, only the content of the div is rendered. Effectively, the tag helper does nothing. The `ModelOnly` option results in `ModelState` errors that apply to named form fields (property-level errors) being included in the message as an unordered list of error messages. When you specify `All`, model-level errors (i.e., those that don't apply to a particular form field) are included along with the property-level errors you have been generating through the validation attributes. You will look at adding a model-level entry when you examine `ModelState` in more detail later.

The content of the validation summary tag helper is visible by default, so if you want to include a default error message, you should ensure it is hidden. You can use the `validation-summary-valid` CSS class applied to the rendered div element to manage that:

```
.validation-summary-valid{ display: none };
```

If there are validation errors, that class is removed from the element and replaced with `validation-summary-errors`.

5.3.3 Server-side validation

Because it is so easy to circumvent client-side validation, server-side validation is included as part of the ASP.NET Core validation framework. Once property values have been bound on the server by the model binder,
