Summary

- Forms can be submitted using both `POST` and `GET` methods.
- Values submitted using `GET` are included in the URL as query string values.
- Values submitted using `POST` are included in the request body.
- Model binding takes values from HTTP requests (sources) and assigns them to handler method parameters and public `PageModel` properties decorated with the `BindProperty` attribute (targets).
- The name attribute in the form control must match the name of the binding target, whether it is a parameter or property.
- Model binding supports binding to collections.
- Include an index within the control's name attribute to identify individual elements within a collection.
- The indexer can be sequential or explicit.
- Explicit indices are more useful when updating existing items.
- Validation can be performed on the client but must be performed on the server.
- Validation attributes work on both the client and the server.
- You must opt in to client validation by including the required scripts in the page.
- You can write your own validation attributes to handle more complex validation scenarios.
