- Textarea

Each tag helper targets the HTML element it is named after, except the form action tag helper, which targets buttons and input elements that have their `type` attribute set to `submit` or `image`.

This chapter starts by covering the form tag helper to help you understand its role and configure it. We will look extensively at the input tag helper and learn how to control the type of input it renders based on the binding target data type as well as how to use data annotation attributes to fine-tune things when needed.

Select lists, check boxes, and radio buttons seem to raise most form-related questions on technical community support sites and forums, so we will look at how to work with their tag helpers in detail. Finally, we will look at using forms to upload files.

6.1 The form and form action tag helpers

The form tag helper targets the HTML `form` element and has two primary responsibilities. It ensures that a request verification token is included in a hidden field within every form that has its method set to `post`. It also generates the URL for the form's `action` attribute from the values you supply to its custom attributes.
