The form action tag helper targets buttons and inputs with their `type` attribute set to `submit` or `image`. Its role is to set the URL for the `formaction` attribute on those elements, which specifies the location the form should be submitted to. As such, it overrides the form's `action` attribute.

Going forward, when I refer to a tag helper's custom attributes in text, I will omit the `asp-` prefix. Just remember that all framework attributes are prefixed with `asp-`. The custom attributes for generating URLs available on both the form tag helper and the form action tag helper are identical to those on the anchor tag helper I covered in detail in chapter 4, and they work in the same way to construct values based on the application's routing configuration:

- `page`
- `page-handler`
- `route-*`
- `all-route-data`
- `host`
- `protocol`
- `area`

If you include an `action` attribute in a form element and any of these custom routing attributes, the framework will raise an error. The form tag helper uses the values passed to these custom attributes to generate an `action` attribute, similar to how the anchor tag helper generates an `href` attribute from the same custom routing attributes. You can either explicitly set the URL via the `action` attribute yourself or use tag helper attributes
