Table 6.1 Mapping between .NET data types and the type attribute generated by the input tag helper

.NET type	HTML input type
`string`	`text`
`bool`	`checkbox`
`int, byte, short, long`	`number`
`decimal, double, float`	`text`
`DateTime`	`datetime-local`
`IFormFile`	`file`

To test this out, add a new folder to the Pages folder named PropertyManager. This will house pages for managing details of rental properties available on the website. Then add a new Razor page named Create.cshtml. Add the following public properties to the `PageModel` representing information about a rental property that allows users to work with a range of .NET types.

Listing 6.2 The `CreateModel` for the Property Manager

```
public class CreateModel : PageModel
{
    [BindProperty]
    public string Name { get; set; }
    [BindProperty]
    public int MaxNumberOfGuests { get; set; }
    [BindProperty]
    public decimal DayRate { get; set; }
    [BindProperty]
    public bool SmokingPermitted { get; set; }
    [BindProperty]
    public DateTime AvailableFrom { get; set; }
}
```

Next you change the Create.cshtml file to include a form, using tag helpers for each of the `PageModel` properties, so the code looks like the following.
