feature of MVC, where a selection of which particular action to execute on a controller can come down to the parameters the action method takes as determined from the collection of posted values.

If you don’t want a hidden field to be rendered, the workaround is to avoid using the tag helper to render your check box for Boolean properties. In these cases, use plain HTML instead.

6.2.2 Using data annotation attributes to control presentation

Residing in the `System.ComponentModel.DataAnnotations` namespace, data annotation attributes provide a way for you to add extra information, or *metadata*, to a type. Various component frameworks within .NET can use this additional information to influence their behavior. Data annotation attributes are widely used with forms in Razor Pages to influence validation, as you have already seen, and presentation. This section looks at how attributes can be used to influence the HTML generated as part of a form. Two attributes are of particular interest in respect to managing the UI: the `DataTypeAttribute` and the `DisplayAttribute`.

USING THE DATATYPEATTRIBUTE TO INFLUENCE THE RENDERED INPUT TYPE

The `DataTypeAttribute` enables you to specify the name of a more specific type than the .NET type system provides for and associate that type with a property. Input tag helpers will use the metadata you specify to override the value generated for the input tag helper’s `type` attribute, resulting in UI behavior that is unique to the specified type. For example,
