```
[BindProperty]
[DataType(DataType.Time)]
public  DateTime ArrivalTime { get; set; }

[BindProperty, DataType(DataType.Time)]
public  DateTime DepartureTime { get; set; }
```

Most leading browsers support the `week` and `month` inputs that enable the user to specify a week of the year or a month. These input types don't have matching `DataType` enumeration values. Instead, you can use the `DataType` attribute's constructor that takes a string to set input types to these options and any others that aren't covered in table 6.2:

```
[DataType("week")]
public  DateTime ArrivalWeek { get; set; }
```

In addition to the `DataType` enumerations, there are similarly named standalone attributes:

- `EmailAddress`
- `Phone`
- `Url`

While these also influence the value assigned to the rendered `type` attribute, they inherit from `ValidationAttribute` and take part in validation, as you saw in the last chapter. `System.ComponentModel.DataAnnotations` is not the only place these types of attributes can be found. `HiddenInput` is another standalone attribute that belongs to the MVC framework; it can be found under the `Microsoft.AspNetCore.Mvc` namespace. When applied to a `PageModel` property, the associated input will be rendered with its `type` attribute set to `hidden`.
