enables you to apply the format string to the property. The format is applied wherever the property is used (assuming that the location is one where the framework recognizes and applies data annotation hints). The format string is specified via the attribute's `DataFormatString` property, and another property, `ApplyFormatInEditMode,` must be set to `true` for the format string to be applied in an editable setting, such as a form input:

```
[BindProperty, DisplayFormat(DataFormatString = "{0:yyyy-MM-ddTHH:mm}",
ApplyFormatInEditMode = true)]
public DateTime AvailableFrom { get; set; } = DateTime.Now;
```

Alternatively, you can use the input tag helper's `format` attribute to control the format on individual input controls:

```
<input asp-for="AvailableFrom" asp-format="{0:yyyy-MM-ddTHH:mm}" />
```

Having applied the format string shown in these examples, only the hour and minute elements of the time are available to be set in the browser (figure 6.4).
