❶ Change the SelectedCity from a string to an int.

❷ Add a string property named Message.

❸ Assign the Cities from a new private GetCityOptions method.

❹ Get details of the selected city from data generated by the GetCityOptions method.

❺ Add a private method for generating the cities, so the logic is centralized in one place.

The only change required to the Razor page is including the `Message` property, so you can see confirmation of which city was selected. I place this at the top of the page, before the opening `form` element:

```
<p>@Model.Message</p>
```

Run the page and select a city. Once you submit the form, you will notice the details of the chosen city are rendered to the browser (figure 6.8).

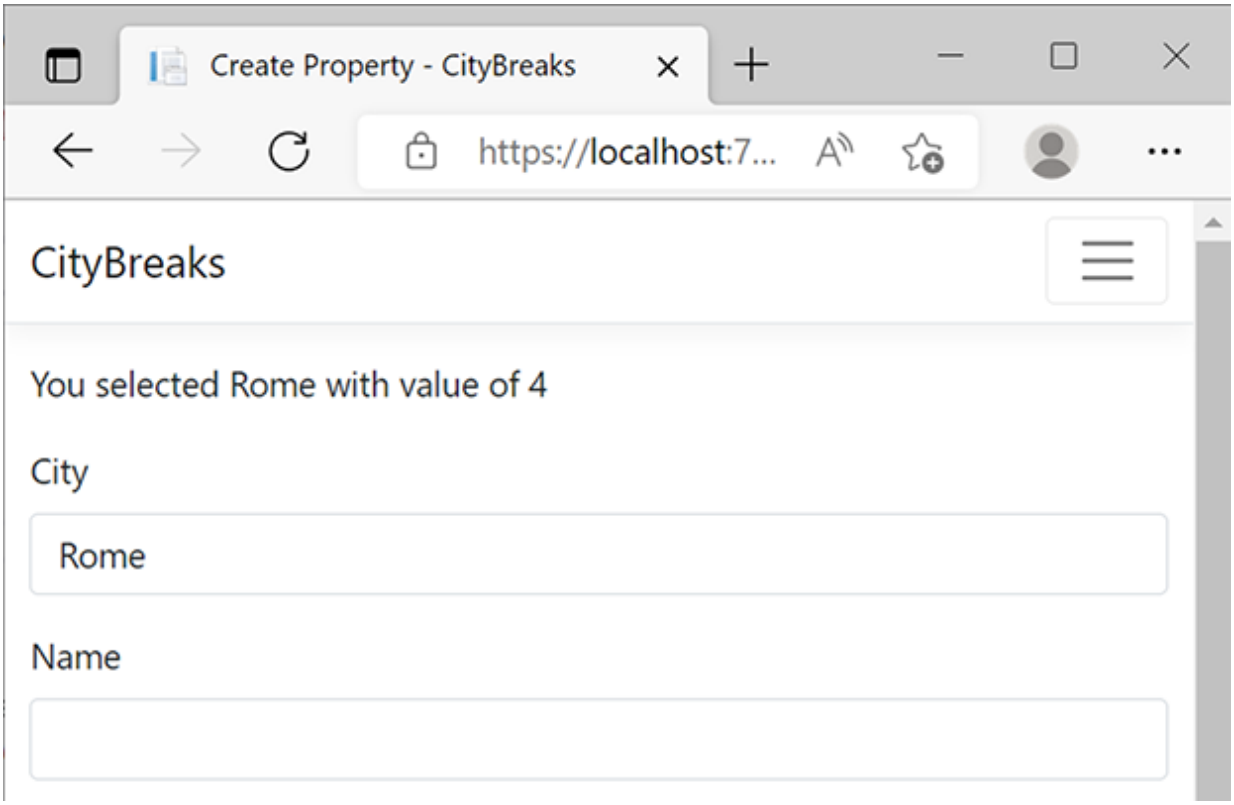

Figure 6.8 Details of the selected city are rendered to the browser.
