

Figure 6.10 Select with `multiple` attribute applied

The select tag helper automatically renders the Boolean `multiple` attribute if the property is bound to be a collection. To be accurate, it renders `multiple="multiple"`, but the mere presence of the `multiple` attribute is all that is required to enable multiple selection. Most browsers ignore any values passed to the `multiple` attribute.

When a user arrives on the website, they may not have decided which city to visit yet. They might want to view various options. You can provide them with a way to easily select multiple options by binding a collection property to a select tag helper. Let's explore this by adding a selection form for the user on the site's home page. Open the Index.cshtml.cs file in the Pages folder, and add the following public properties to the `IndexModel`, representing the binding for the select tag helper (`int[] SelectedCities`), and the options with a message.

Listing 6.12 The `PageModel` properties for the multiple select list

```
[BindProperty]
[Display(Name = "Cities")]
public int[] SelectedCities { get; set; }
public SelectList Cities { get; set; }
public string Message { get; set; }
```

Now copy the same private `GetCityOptions` method from the Create Property page you have been working with to generate the `SelectList`, and add it to the `IndexModel`.
