five, and you also have to handle properties that have not been rated. So you will create an enumeration with members that will cover all options. Add a new C# class file to the Models folder named Rating.cs, and change the class to an `enum`.

Listing 6.19 The `Rating` enumeration

```
public enum Rating
{
    Unrated, OneStar, TwoStar, ThreeStar, FourStar, FiveStar
}
```

The next step is to add a property to the `CreateModel` in the PropertyManager folder:

```
[BindProperty]
public Rating Rating { get; set; }
```

You want to be able to reference this type in the Razor page, so you need to make the `CityBreaks.Models` namespace available to it. If you cast your mind back to chapter 3, you will recall you can achieve this globally by adding a suitable `using` directive to a ViewImports file, so open the one in the Pages folder, and do just that by adding the bold code in the following listing.

Listing 6.20 Adding a using directive to `ViewImports`

```
@using CityBreaks
@using CityBreaks.Models
@namespace CityBreaks.Pages
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers
```

The `Html.GetEnumSelectList` method is provided, so you can easily bind an enumeration as the data source for a select list. You are going to use that method in the `asp-items` attribute on a select tag helper you
