The `Html.GetEnumSelectList` method can be used anywhere in a Razor page to convert an enumeration to an `IEnumerable<SelectListItem>`. You can iterate over these and render an input for each one. You can use the input tag helpers' `for` attributes to bind the radio control group to the `Rating` property, but you must set the `type` explicitly with this input tag helper. There is no mapping from a .NET type to the radio control. When you explicitly set HTML attributes on a tag helper, the tag helper honors your assignment. You have done the same thing with the `id` attribute, which the tag helper normally generates. You will need to set the value yourself. Otherwise, all inputs will have the same autogenerated ID of `"Rating"`, and you cannot have multiple elements in the same document with the same ID value. So you have constructed unique values by concatenating the rating's numerical value to `"rating-"`, resulting in `"rating-0"`, `"rating-1"`, and so on. Figure 6.15 shows the final rendered collection of radio buttons.
