have to take into account differences between browser capabilities when writing your code. On the other hand, client-side applications can result in rich user experiences and even closely emulate desktop applications. Great examples of applications rendered mainly on the client include Facebook and Google Docs.

Applications that render their HTML on the server can take advantage of any framework or language supported by the server and have as much processing power available to them as the server can provide. That means the HTML generation is controllable and predictable. In addition, all application logic is deployed to the server itself, meaning it is as secure as the server. And since the output of the processing should be standards-compliant HTML, you shouldn’t need to worry so much about browser quirks.

1.1.3 Cross-platform functionality

Razor Pages applications can be created and deployed on a wide variety of platforms. Windows, Linux, macOS, and Docker are all supported. If you want to create your application on your super-thin and expensive MacBook Air or Surface Pro, you can. Or if you are more at home with a reconditioned ThinkPad running Debian or Ubuntu, no problem. And you can still share your source code with colleagues who are working with different platforms. Your deployment options are equally unrestricted, which means you can take advantage of the best deals on offer from your web-hosting company.

1.1.4 Open source

Back in the day, when I was first honored as a Microsoft most valuable professional (MVP, an annual award made to people who Microsoft judges to have made significant contributions to the community through sharing their technical expertise), one of the benefits of the award was gaining direct
