Next change the code in the Razor page that renders the service values as follows.

**Listing 7.10 Rendering values from both services**

```
<p>The first transient service returned @Model.Value</p>
<p>The second transient service returned @Model.SecondValue</p>
```

Finally, change the registration in Program.cs to use the transient lifetime:

```
builder.Services.AddTransient<LifetimeDemoService>();
```

Run the application, navigate to /lifetime-demo, and note that the values rendered to the browser are different. Every time you refresh the page, they change, confirming that each service is instantiated every time they are requested.

## *SCOPED SERVICES*

The final lifetime option is the scoped lifetime. As mentioned previously, in ASP.NET Core web applications, a *scope* is an HTTP request, which means *scoped services* are created once per HTTP request. What actually happens is that an instance of the container is created for each HTTP request and is destroyed at the end of the request. Scoped services are resolved by this scoped container and are consequently destroyed when the container is destroyed at the end of the scope. Scoped services differ from transient services in that only one instance of a scoped service is resolved per scope, whereas multiple instances of a transient service can be instantiated.

Once instantiated, the scoped service is reused as many times as needed during the scope (request) and disposed of at the end of the request. Each
