Some services provided by the framework are designed to assist with the generation of HTML. One example is the `IHtmlLocalizer` service, which is used for localizing snippets of HTML in web applications that need to handle multiple languages. It serves no purpose outside of a Razor page or view. It is possible to inject this service into the `PageModel` of a page that needs it and then assign it to a public property, so it is accessible via the `Model` in the Razor page itself. But a better solution is to simply inject the service directly into the page using the `@inject` directive.

Listing 7.16 Using the `@inject` directive to inject services into a Razor page

```
@page
@inject IHtmlLocalizer<IndexModel> htmlLocalizer  ❶
@model IndexModel
@{
    ViewData["Title"] = "Home page";
}

<div class="text-center">
    <h1>Welcome</h1>
    <p>@htmlLocalizer["Intro"]</p>                ❷
</div>
```

❶ The IHtmlLocalizer<T> service is injected using the @inject directive and assigned to the variable htmlLocalizer.

❷ The localizer service is used to localize a snippet of HTML identified as "Intro".

I should stress that this approach is fine when you are only using it for HTML-based services. You should not inject any services containing business logic directly into the page. We keep our business logic away from HTML, don’t we?

7.3.2 Method injection
