EF Core enjoys tooling support within Visual Studio that can help you quickly generate CRUD pages based on your application model. While the results are not perfect, they provide a significant head start to developing the more mundane parts of your application. The scaffolding support is also available to non-Visual Studio users from the command line. You will see this in action later.

8.1.2 How does EF Core work?

At a fundamental level, EF Core creates a conceptual model of how your domain objects and their properties—your application model—map to tables and columns in a database. It also understands the associations between domain objects and can map those to database relationships. It is a drop-in data layer for your application, sitting between the domain (on the left-hand side of figure 8.1) and the data store (on the right-hand side of figure 8.1).

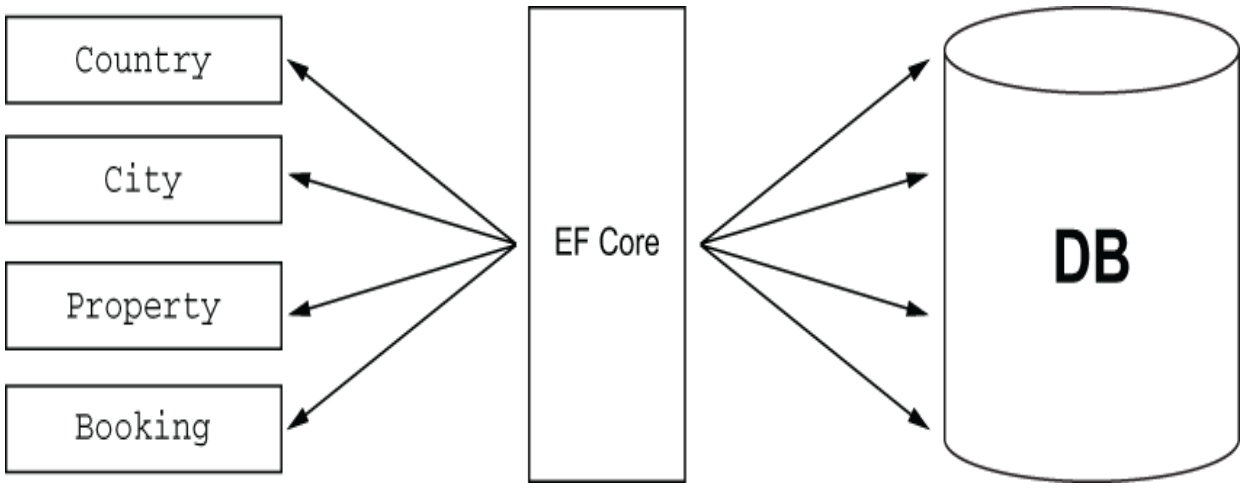

Figure 8.1 EF Core sits between the domain objects on the left and the database on the right and maps objects and their properties and associations to database tables, columns, and relationships.

EF Core manages communication between your business objects and the data store. Language-Integrated Query (LINQ) will help you create query
