```
    public string Name { get; set; }
    public Country Country { get; set; }     ❶
}
```

❶ Country is a navigational property.

This is all that is needed for EF Core to infer a one-to-many relationship between the `Country` and `City` entities, where the `Country` is the principal in the relationship and the `City` is the dependent. In this example, the `Country` property is referred to as a *reference navigation property*, which has a *multiplicity* (the potential number of items at one end of a relationship) of zero or one. More commonly, EF Core relationships are *fully defined*, having properties representing each end of the relationship and a property representing the foreign key value. In listing 8.2, you add a property representing the `CountryId` foreign key to the `City` class and a collection navigation property to the `Country` class representing all the cities that could belong to a single country. As a best practice, you should always instantiate collection navigation properties as part of their declaration, so you can avoid having to test for `null` when accessing them in code.

Listing 8.2 Fully defined one-to-many relationship between `Country` and `City`

```
public class City
{
    public int Id { get; set; }
    public string Name { get; set; }
    public int CountryId { get; set; }                    ❶
    public Country Country { get; set; }                  ❷
}

public class Country
{
    public int Id { get; set; }
    public string CountryName { get; set; }
    public string CountryCode { get; set; }
```
