add some `using` directives to bring in `Microsoft.EntityFrameworkCore` and `CityBreaks.Data` before adding the following code.

Listing 8.7 Configuring the `CityBreaksContext`

```
builder.Services.AddDbContext<CityBreaksContext>(options =>
{
    options.UseSqlite(builder.Configuration.GetConnectionString
    ➥ ("CityBreaksContext"));
});
```

The `GetConnectionString` method locates the specified connection string within the `ConnectionStrings` section of appSettings.json, while the `UseSqlite` method sets up the correct database provider for EF Core to use.

You have your context and have registered it as a service. At the moment, it's pretty useless; it's like having an empty database. You will need some database tables represented in the context by `DbSet<TEntity>` properties, where `TEntity` is the entity you want the table to represent. Figure 8.4 illustrates the relationship between entities, `DbSet`s and the database.
