Start by creating a new folder in the Data folder, naming it Configurations. Add a C# class file to the new folder, named CountryConfiguration, with the following code.

Listing 8.9 The `CountryConfiguration` class

```
using CityBreaks.Models;
using Microsoft.EntityFrameworkCore;
using Microsoft.EntityFrameworkCore.Metadata.Builders;

namespace CityBreaks.Data.Configuration;
public class CountryConfiguration : IEntityTypeConfiguration<Country>    ❶
{
    public void Configure(EntityTypeBuilder<Country> builder)            ❷
    {
        builder.Property(x => x.CountryName)
            .HasMaxLength(50);                                            ❸
        builder.Property(x => x.CountryCode)
            .HasColumnName("ISO 3166 code")                               ❹
            .HasMaxLength(2);                                             ❹
    }
}
```

❶ The class implements IEntityTypeConfiguration<TEntity>.

❷ Implement the Configure method, as required by the interface.

❸ Use the HasMaxLength method to constrain the length of the text field for the CountryName property.

❹ Map the CountryCode property to a column named "ISO 3166 Code" and constrain its size.

String properties conventionally map to `nvarchar(max)` datatypes in SQL Server. You have used the `HasMaxLength` method to apply a limit to the size of a text-based column in databases that support it. SQLite doesn't support this method, so unless you are working with SQL Server instead, this configuration will have no effect. Nevertheless, the `HasColumnName` method will work in any database and map the `CountryCode` property to the `"ISO 3166 code"` column. You can see the fluent API with the `HasMaxLength` method chained to the
