8.2.2 Adding migration tools

Before creating a migration, you need to add the necessary package to the project that contains the commands for managing them. Two packages are available, each one having a different set of commands. The one you use will depend on what tool you want to use to execute the migration commands.

If you are a Visual Studio user, you can use the Package Manager Console; in that case you will want the PowerShell commands contained in the `Microsoft.EntityFrameworkCore.Tools` package. Alternatively, you can use the cross-platform CLI commands available in the `Microsoft.EntityFrameworkCore.Design` package instead. Once you have selected your package, you can use whichever method you prefer from those covered earlier to add the package to your project. If you are using the CLI commands, you must also ensure that the `dotnet-ef` tools are installed globally, which you can do using the following command:

```
dotnet tool install --global dotnet-ef
```

8.2.3 Creating and applying a migration

Once the tools and relevant package are installed, you can create your first migration. You will use one of the following commands:

```
[Powershell]                          ❶
add-migration Create                  ❶
[CLI]                                 ❷
dotnet ef migrations ad Create        ❷
```
