also have a great example of how loose coupling enables changes to be made to the application with a minimum of fuss. You haven't had to touch the code in either of the Create page's files to get it to work with a database. All you had to do was change the service registration.

8.3.2 Selecting single records

Now that you have a good working example of selecting multiple records, you will amend the City page to retrieve a single record based on a value passed in the URL. First, you need to update the `ICityService` to include a new method called `GetByNameAsync`, which takes a string as a parameter and returns a `Task<City>`.

Listing 8.17 Adding new method to the `ICityService`

```
public interface ICityService
{
    Task<List<City>> GetAllAsync();
    Task<City> GetByNameAsync(string name);
}
```

You have two services that implement this interface; you won't be using the `SimpleCityService` again, so you can safely delete it or use the `NotImplementedException` to create a stub for the method that satisfies the interface contract as far as the compiler is concerned:

```
public Task<City> GetByNameAsync(string name) => throw new
➥ NotImplementedException();
```

If you choose to take the latter route, you will need to remember to do the same for all other methods you add to the `ICityService` interface going forward. Next you will provide a working implementation in the `CityService` class.
