`CityModel` class, so replace the content of \Pages\City.cshtml.cs with the following code.

Listing 8.19 Revised `CityModel` code

```
using CityBreaks.Models;
using CityBreaks.Services;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;

namespace CityBreaks.Pages;

public class CityModel : PageModel
{
    private readonly ICityService _cityService;
    public CityModel(ICityService cityService)
    {
        _cityService = cityService;
    }

    [BindProperty(SupportsGet = true)]
    public string Name { get; set; }
    public City City { get; set; }

    public async Task<IActionResult> OnGetAsync()
    {
        City = await _cityService.GetByNameAsync(Name);
        if(City == null)
        {
            return NotFound();
        }
        return Page();
    }
}
```

You inject the `ICityService` and use it to retrieve a city matching the name passed to the page in the URL. You should anticipate the result may be `null`, in which case, you will let the user know there is no matching page. All that remains now is displaying the details of the matching record if one is found.

To add some visual interest to the details, you are going to incorporate some free icons from Font Awesome (https://fontawesome.com). You will need to add a link to a CDN version of their icons in the Pages\Shared \
