implements the page controller approach, with the controller being a class that derives from `PageModel`.

Front controllers in the ASP.NET MVC framework are individually responsible for a lot more than page controllers (figure 1.4). They have to coordinate processing for all of the actions related to a specific business area —create, update, delete, get lists, get details, and so on. Over time, front controllers can grow to hundreds, if not thousands, of lines of code. The number of dependencies they take increases, which is a sure sign that the controller is doing too much. They become difficult to manage. Page controllers, on the other hand, are a lot simpler, only having to manage processing for their individual page. Some of them barely have any code in them at all.
