Scaffolding is a technique used to generate code at design time to support several common application scenarios when working with EF Core. The scaffolding tool supports the generation of Razor pages that interact with the database using the templates in table 8.1.

Table 8.1 The templates available to the scaffolding tool

Template	Description
`Create`	Generates a Razor page with a form for creating the specified model class and `PageModel` handlers complete with code for saving to a database
`Edit`	Generates a Razor page with a form for editing the specified model class and `PageModel` handlers complete with code for retrieving the specified entity and saving changes to a database
`Delete`	Produces a page that displays details of the selected entity and a form with a hidden field that passes the key value of the entity to a handler method that removes it from the database
`Details`	Produces a page that displays details of the selected entity
`List`	Produces a page that displays details of all instances of the selected entity in a table

In addition, the scaffolding tool supports an *empty* template, which is the equivalent of what you have seen whenever you've added a new Razor page to your application from either the Visual Studio dialog or the command line. The code that is generated by the scaffolding tool is rarely production ready. It provides a starting point only. You will use the tool to generate all CRUD pages for the `Property` class and then review the generated code to understand its shortcomings and what you will need to do to resolve any issues.

Before using the scaffolding tools, you must install a NuGet package that contains the templates: `Microsoft.VisualStudio.Web.CodeGeneration.Design`. If you are using Visual Studio, the IDE will attempt to add a reference
