to the latest stable version of this package when you use scaffolding. However, in my experience, Visual Studio reports an error after it has installed the package, requiring you to specify your scaffolding selection again. For that reason, I usually add the package reference manually. Suppose you want to use the command line for scaffolding. In that case, you will need to add the package manually anyway, using any available methods we have already covered for managing NuGet.

8.4.1 Visual Studio scaffold instructions

Scaffolding is built into Visual Studio and is accessible from the Add dialog. Right-click the Pages\PropertyManager folder, and choose Add from the context menu. Then choose New Scaffolded Item... from the second menu group. Select Razor Pages from the dialog that appears, and then select Razor Pages using Entity Framework (CRUD). Next click the Add button. In the next dialog, select Property (CityBreaks.Models) as the Model class and CityBreaksContext as the Data context class. Leave the other options as their defaults; that is, Reference Script Libraries and Use a Layout Page should both be selected. Leave the layout page input empty. Refer to figure 8.10.
