There are two more things to do before you can test this out. The first is altering the `GetAllAsync` method in the `PropertyService` to exclude properties that have a value assigned to their `Deleted` property.

Listing 8.39 Excluding deleted properties from the result set

```
public async Task<List<Property>> GetAllAsync() =>
    await _context.Properties
    .Where(p => !p.Deleted.HasValue)
    .Include(x => x.City)
    .ToListAsync();
```

Then you alter the `IndexModel` class in the PropertyManager\Index.cshtml.cs file to take a dependency on `IPropertyService` instead of the context, so you can use your new method to populate the page.

Listing 8.40 The revised `PropertyManager IndexModel`

```
public class IndexModel : PageModel
{
    private readonly IPropertyService _propertyService;

    public IndexModel(IPropertyService propertyService)
    {
        _propertyService = propertyService;
    }

    public IList<Property> Property { get;set; }

    public async Task OnGetAsync()
    {
        Property = await _propertyService.GetAllAsync();
    }
}
```

Now run the application, and navigate to /property-manager. Observe the first property in the list. If you are using the seed data provided with the last chapter's downloads, the first property in the listing should be Hotel Paris.
