available to your code. Then you use the `AddAuthentication` method to add authentication services.

Listing 9.1 Adding authentication services to the service container

```
builder.Services.AddAuthentication(CookieAuthenticationDefaults
➥ .AuthenticationScheme)
    .AddCookie();
```

That's it. You have added very basic cookie authentication. You must specify the name of a default *scheme*, which represents the registered authentication handler and its options. In this case, you have used `CookieAuthenticationDefaults.AuthenticationSchxme` to represent the name of the scheme. It is a constant that resolves to `Cookies`.

The next stage is to add the authentication middleware. You will do this by calling `app.UseAuthentication()` in the request pipeline. However, the positioning of this call is crucial to authentication working properly. It must be placed *after* routing is added but *before* endpoints are added by the `MapRazorPages` call. The default template includes a call to `UseAuthorization`, which adds authorization middleware. You must add authentication before that too; the end result is shown in the following listing.

Listing 9.2 Adding authentication middleware after routing and before authorization

```
app.UseRouting();

app.UseAuthentication();      ❶
app.UseAuthorization();

app.MapRazorPages();
```

❶ Add authentication after routing and before authorization and endpoint middleware.
