While you are looking at the data within the `AspNetUsers` table, you can take a quick look at the schema for the table, which mirrors the `IdentityUser` class properties. Some of the fields are related to account status, while others relate to the user's profile. The profile fields are limited to those required for account management—name, email, and phone number—so tokens and confirmations can be sent by email or SMS. If you are operating an e-commerce site, you will also want to store the user's address for delivery and, possibly, a different billing address. You might want to store their date of birth, so you can send them a card or limit sales of age-restricted products and services. You will look at how to customize your `IdentityUser` to enable that, along with other Identity-related customizations, in the remainder of this chapter. Before you do that, click the Sign Out link, and follow the instructions to sign out of the application to confirm the sign-out feature works.

## *9.3 Customizing Identity*

Now that you have Identity and its UI working, we can look at some options for customizing various aspects to suit your own application requirements. You have already seen the default password options; now we will explore how to control those and other options related to how Identity works. Then we will look at customizing your implementation of the `IdentityUser`, so you can store more information than the base type caters for. Finally, we will look more closely at the default UI and understand how you can control its look, feel, and behavior.

### *9.3.1 Customizing Identity options*

The `IdentityOptions` class represents all the options you can use to configure the Identity system. It has a number of properties providing access to options that relate to specific areas of Identity. The properties you are most likely to work with are shown in table 9.1.
