Table 9.2 shows the two properties of the `UserOptions` class that represent configurable user options. The default Identity UI package uses email addresses as usernames, which must be unique. Bearing this in mind, if you were to restrict the allowed characters further and remove the symbols, users would not be able to register because email addresses require at least two symbols. These options will only take effect if you change the way users are registered—which is relatively easy to do, as you will see later.

Table 9.2 The `UserOptions` properties

Property	Description
`AllowedUserNameCharacters`	Specifies the range of characters permitted in a user's name. Defaults to a-z, A-Z, 0-9, and the symbols -._@+.
`RequireUniqueEmail`	Boolean. If set to true, email addresses must be unique.

CONFIGURING PASSWORD OPTIONS

Passwords are becoming a hot topic. Microsoft has been moving away from passwords in favor of biometrics (e.g., fingerprints and facial and speech pattern recognition) along with security codes sent to users via SMS for a while. Nevertheless, passwords are still central to the default implementation of Identity. As already hinted at, there are a number of options for configuration via the `PasswordOptions` object (table 9.3).
