Name	Default	Description
`RequireConfirmedAccount`	`false`	Determines whether conditions specified by the `IUserConfirmation<TUser>` interface need to be met to enable sign-in. The default implementation of this interface specifies that an email address is required.
`RequireConfirmedEmail`	`false`	Determines whether a confirmed email is needed to enable the user to log in.
`RequireConfirmedPhoneNumber`	`false`	Specifies whether a confirmed phone number is needed to enable the user to log in.

The Identity UI package does not support phone number confirmations by default. So if you set this to `true`, you will lock all users out of the application. If you want to enable password reset or other features that rely on email addresses, it is a good idea to enable `RequireConfirmedEmail`. We will look at how you can enable and test this locally without requiring access to an email provider a bit later.

CONFIGURING LOCKOUTOPTIONS

Primarily as a defense against brute force attacks, you can enable account lockout in the event of multiple failed attempts to sign in. The configurable options are detailed in table 9.5.
