The Identity UI is developed as a *Razor class library* (RCL), enabling it to be deployed as a NuGet package and plugged into applications that want to use it. RCLs can contain Razor pages, static assets, and even MVC controllers and views. Developing RCLs is an advanced topic not covered in this book, but you can refer to the official documentation for more details: http://mng.bz/O6Vw. The contents of an RCL are overridable, as long as you replicate the file structure within the RCL. Physical files on disk take precedence over the content of the RCL.

The Identity UI includes support for scaffolding to generate physical copies of some, if not all, of the Identity pages. The scaffolded pages replicate the file structure within the RCL, which means they automatically override the default UI. Identity scaffolding depends on the same package you installed when you generated the CRUD pages in chapter 8: `Microsoft.VisualStudio.Web.CodeGeneration.Design`. If you are using Visual Studio, the Identity scaffolder is accessible via the Add... New Scaffolded Item dialog (figure 9.9).
