Authorization within a Razor Pages application is provided by a number of services, including an `IAuthorizationService`. These must be added to the service container at application startup. A convenience method, `AddAuthorization`, takes care of adding all the required services:

```
builder.Services.AddAuthorization();
```

Authorization middleware is enabled by default in the web application template by the inclusion of `app.UseAuthorization()` in the `Program` class.

Authorization depends on knowing who the user is and what they are trying to do as well as, in the case of request-based authorization, which page they are trying to reach. As established in chapter 4, `EndpointRouting` middleware, which is added to the pipeline by `UseRouting`, is responsible for determining which page the user is trying to reach. In the last chapter, you learned that authentication middleware (added with `UseAuthentication`) is responsible for establishing who the user is. Finally, `MapRazorPages` is where the selected page is executed. This middleware flow is illustrated in figure 10.1.
