storage mechanism for roles. In your case, that's the SQLite database. You won't work directly with the `RoleStore`, generally; you will use the `RoleManager` for that. In the next couple of sections, you will look at creating a simple admin area for creating and viewing roles with the `RoleManager` and assigning them to users.

10.2.1 Viewing roles

Start by adding a folder to the Pages folder named RolesManager. Within that, add a new Razor page named Index.cshtml. You will inject the `RoleManager` service into the `PageModel` class constructor and use its `Roles` property to populate a public `List<IdentityRole>` property.

Listing 10.8 The RolesManager `IndexModel` class

```
using Microsoft.AspNetCore.Identity;
using Microsoft.AspNetCore.Mvc.RazorPages;

namespace CityBreaks.Pages.RolesManager
{
    public class IndexModel : PageModel
    {
        private readonly RoleManager<IdentityRole> _roleManager;     ❶
        public IndexModel(RoleManager<IdentityRole> roleManager)     ❶
        {                                                            ❶
            _roleManager  = roleManager;                             ❶
        }                                                            ❶
        public List<IdentityRole> Roles { get; set; }                ❷
        public void OnGet()
        {
            Roles = _roleManager.Roles.ToList();                     ❷
        }
    }
}
```

❶ Inject the RoleManager<TRole> service into the IndexModel via its constructor, and assign it to a private field for later use.
