```
            }
            await GetOptions();
            return Page();
        }

        public async Task GetOptions()
        {
            var users = await _userManager.Users.ToListAsync();
            Users = new SelectList(users,
            ➥ nameof(CityBreaksUser.Id), nameof(CityBreaksUser.UserName));
        }
    }
}
```

You use the `AddClaimAsync` method of the `UserManager` to assign additional claims to the user. It takes a user and a claim as arguments. You use the bound properties to construct those. This time, because you are binding the user's unique identifiers to the select list, you use the `FindByIdAsync` method to get the user from the `UserManager`. Remember, you used `FindByNameAsync` previously. You construct a new claim from the type and value passed in. Claims don't have to have a value assigned, but the value cannot be `null`, so you pass in `String.Empty` if no value is provided. Once the claim is added, you are directed to the Index page, where you can see your new claim displayed.

Run the application, and navigate to /claims-manager /assign. Add a new claim to anna@test.com. The type should be `Admin`, and the value should be left empty (figure 10.5). Having assigned a claim, the next step is to use it as part of an authorization policy.
