Method	Description
`RequireClaim(string claimtype)`	The user must have the specified claim.
`RequireClaim(string claimtype, params string[] allowedValues)` or `RequireClaim(string claimtype, IEmumerable<string> allowedValues)`	The user must have the specified claim with one of the specified values.
`RequireUserName`	The user must have the specified name.
`RequireAuthenticatedUser`	The user must be authenticated.
`RequireAssertion`	Takes a delegate that represents an assertion to be tested to determine authorization status.

The variations of the `RequireClaim` method create a `ClaimsAuthorizationRequirement` with a handler that returns `true` if the specified claim exists and, if values are specified, that at least one of them is found. You can test this by changing the code for the existing policy to use the `RequireClaim` method instead of `RequireRole`:

```
builder.Services.AddAuthorization(options =>
{
    options.AddPolicy("AdminPolicy", policyBuilder =>
    ➥ policyBuilder.RequireClaim("Admin"));
});
```

You can also apply this policy to pages individually by passing the name of the policy to the `Policy` property of the `AuthorizeAttribute`:

```
[Authorize(Policy="AdminPolicy")]
public IndexModel : PageModel
```
