```
        policyBuilder.AddRequirements(new ViewRolesRequirement(months: -6)));
});
```

CREATING A SEPARATE HANDLER CLASS

Building a combined requirement and handler is fine for simple use cases, but more often, you may want to create your handler as a separate class to enable reuse. When you do this, there are a couple of changes you need to make to your general approach. The existing requirement itself is trimmed down to just an implementation of `IAuthorizationRequirement`.

Listing 10.21 The standalone requirement class

```
public class ViewRolesRequirement : IAuthorizationRequirement
{
    public int Months { get; }
    public ViewRolesRequirement(int months)
    {
        Months = months > 0 ? 0 : months;
    }
}
```

Create a new folder named AuthorizationHandlers, and add a new class to it named `ViewRolesHandler`. This is the separate handler class. It implements `IAuthorizationHandler`. Since the handler class itself isn't scoped to a specific requirement, you have to access the `PendingRequirements` property of the `AuthorizationHandlerContext` to filter to the right type of requirement. The `PendingRequirements` property gets all the requirements that have yet to be marked as succeeded.

Listing 10.22 The `ViewRolesHandler` separated into a class

```
public class ViewRolesHandler : IAuthorizationHandler
{
```
