So far we have concentrated on authorizing endpoints (pages). A user is either authorized to access an endpoint, or they aren't. Sometimes you will want to perform authorization based on a resource that is exposed at the endpoint. For example, you might have a situation in which any authorized user can add a new property (the resource), but only the creator can edit a property. That means both you and I can add properties, but you cannot edit mine, and I cannot edit yours. To apply this kind of authorization, you need to know who created the property. That can only be done by executing the endpoint and loading the property from the database. In this section, you will look at how to approach this task using an authorization handler that takes the resource as a parameter.

Before you can do that, you need to assign creators to properties. Open the `Property` class, and add the following two properties:

```
public string CreatorId { get; set; }
public CityBreaksUser Creator { get; set; }
```

The `CreatorId` is a string property because it will hold the user's identity value. By default, that is a GUID. Add a new migration named `AddedCreatorToProperty`:

```
[Powershell]
add-migration AddedCreatorToProperty
[CLI]
dotnet ef migrations add AddedCreatorToProperty
```

Apply the migration, and then update a number of properties in the database, so the `CreatorId` column contains the `Id` value of your users. I manually applied the `Id` of my three users to the first 20 records in the database table (figure 10.8). Once this has been done, you are ready to go.
