only provide edit links if the user created the property and delete links if they are in the `Admin` role. In the final section of this chapter, you will use the `IAuthorizationService` to manage the presentation based on the current user and resource.

10.4.2 Applying authorization to the UI

When you want to evaluate authorization in the UI based on resources, use the same `AuthorizeAsync` method on the `IAuthorizationService` as you just used within the `EditModel` within the property manager. You need to make the service available to the Razor page, so you inject it using the `inject` directive. Then you display Edit and Delete links based on the result of the method calls.

The code changes to the PropertyManager \Index.cshtml file are detailed in the following listing. It requires a couple using directives at the top of the page along with the `inject` directive to make the `IAuthorizationService` available.

Listing 10.29 Injecting the `IAuthorizationService` into the index page

```
@page
@model CityBreaks.Pages.PropertyManager.IndexModel
@using CityBreaks.AuthorizationRequirements
@using Microsoft.AspNetCore.Authorization
@inject IAuthorizationService authService
```

The only other required change takes place in the `td` element containing the links. Replace the element with the code in the following listing.

Listing 10.30 Using the IAuthorizationService
