a standard form to a page handler and standalone data. We will pay particular attention to request verification when we do this, remembering it is baked into the Razor Pages framework by default. Finally, we will cover how to work with JSON when interacting with page handlers from client code.

11.2.1 Using a partial page to return HTML

In the first example, you will look at loading snippets of HTML into a page asynchronously. Specifically, you will load details of a property into a Bootstrap modal when the user clicks on the name of a property in a list. You will use partial pages for this exercise. One partial will contain the outline HTML for the modal, the head and foot, which will be included in the existing City page. The modal body will be loaded from the server when the user clicks on a property listing on the city page. You will add client-side code that identifies which property was clicked and then makes a request to a page handler that returns a `PartialResult`, which, if you remember from chapter 3, represents the processing of a partial page. It is perfect for generating fragments of HTML, such as those that might be used for updating regions of pages.

You will create the outline of the modal to start. Add a new cshtml file to the Pages\Shared folder. Remember, there is no template for partial views, so if you are using Visual Studio, you can choose the Razor View > Empty template and then remove the default content. Name the partial file _PropertyModalPartial.cshtml, and replace any existing content with the following code.

Listing 11.1 The `PropertyModalPartial` content based on Bootstrap 5 modal
