_PropertyDetailsPartial.cshtml file. I have not included validation, again, to keep the example simple.

Listing 11.10 The booking form added to the property details partial

```
<form id="booking-form">
    <input type="hidden" asp-for="Property.DayRate" />                ❶
    <div class="form-group">
        <label asp-for="StartDate" class="control-label"></label>
        <input asp-for="StartDate" class="form-control" />            ❷
    </div>
    <div class="form-group">
        <label asp-for="EndDate" class="control-label"></label>
        <input asp-for="EndDate" class="form-control" />              ❷
    </div>
    <div class="form-group">
        <label asp-for="NumberOfGuests" class="control-label"></label>
        <input asp-for="NumberOfGuests" class="form-control"
max="@Model.Property.MaxNumberOfGuests" />                            ❸
    </div>
</form>
```

❶ Include a hidden field containing the selected property's day rate.

❷ Add inputs for arrival and departure dates.

❸ Use the max attribute to limit the numeric input to the maximum number of guests the selected property can accommodate.

You also need to change the model type for the partial. Currently it is a `Property`. You will be changing that to a `BookingInputModel`, so replace the first line of _PropertyDetailsPartial.cshtml with the following:

```
@model CityModel.BookingInputModel
```

Next add a new button to the property modal partial; the partial that acts as a frame for the dynamically loaded property details. Add the bold line in the following listing to the footer element.

Listing 11.11 The `Book` button added to the modal partial
