- `FromQuery`
- `FromHeader`
- `FromBody`
- `FromServices`

When binding parameters from the body, minimal APIs expect the parameter format to be JSON and attempt to deserialize it. Binding from forms is not supported in .NET 6. If you are working with a later release of .NET, you should check the documentation to see if this has changed, although, as you have seen, it is easy enough to serialize a form to JSON on the client before you pass it to the API.

In the following example, you will migrate the booking calculation to a service you will register with the dependency injection system and then add as a parameter to the request handler. This is the recommended way to separate the application logic because it makes it easier to debug and test. First add a new class to represent a booking to the Models folder. The class is named `Booking`, and its properties represent the data required to calculate a booking.

Listing 11.20 The `Booking` class

```
namespace CityBreaks.Models
{
    public class Booking
    {
        public DateTime StartDate { get; set; }
        public DateTime EndDate { get; set; }
        public int NumberOfGuests { get; set; }
        public decimal DayRate { get; set; }
    }
}
```
