Add the following interface to the Services folder. It specifies a method that returns a decimal and takes an instance of the `Booking` class.

Listing 11.21 The `IBooking` interface

```
using CityBreaks.Models;

namespace CityBreaks.Services
{
    public interface IBookingService
    {
        decimal Calculate(Booking booking);
    }
}
```

Add the following implementation of the `IBooking` interface to the Services folder. The code for the `Calculate` method is essentially the same as that currently within the request handler.

Listing 11.22 The `BookingService` class

```
using CityBreaks.Models;

namespace CityBreaks.Services
{
    public class BookingService : IBookingService
    {
        public decimal Calculate(Booking booking)
        {
            var numberOfDays = (int)(booking.EndDate -
            ➥ booking.StartDate).TotalDays;
            var totalCost = numberOfDays * booking.DayRate *
            ➥ booking.NumberOfGuests;
            return totalCost;
        }
    }
}
```

Now you register the service in Program.cs:

```
builder.Services.AddSingleton<IBookingService, BookingService>();
```
