dynamic content, so you can begin to understand what a Razor page actually is. Once you have tested the page to ensure that it works, you will use the site's master template file to add the page to the site navigation.

Then, I discuss the application files generated by the tooling to understand the role each of the generated files plays within your Razor Pages application. This walkthrough will help you understand the basics behind all ASP.NET Core applications.

At the end of the walk-through, we will take a closer look at the primary application configuration: the request pipeline. This is the core of your application. It defines how your application handles requests and delivers responses to clients. You will learn how it is constructed from middleware components and how you can extend it by adding your own middleware.

By the end of this chapter, you should have a good high-level understanding of how a Razor Pages application works, from receiving a request to finally sending HTML back to the client. Then you will be ready to take a deep dive into working with a Razor page and its companion, the `PageModel` class, in chapter 3.

2.1 Creating your first website

This section will cover using the available tools to generate a fully working Razor Pages application rapidly. You will use Visual Studio 2022 Community Edition on Windows 10 and the CLI for non-Windows readers. I discuss using the CLI within Visual Studio Code, although you can use any terminal application to execute CLI commands. So the following sections assume you have your environment installed and working, along with a version of the SDK that supports .NET 6 development. You can test to see
