return types you can use with a minimal API request handler. The static `Results` class, introduced in .NET 6, includes other methods for different return types, which all implement `IResult`. The ones you will use most often in a Razor Pages application are detailed in table 11.1.

Table 11.1 The commonly used methods in the `Results` class

Method	Response type	Description
`Results.Ok`	`application/json`	Produces JSON
`Results.Json`	`application/json`	Produces JSON and enables you to set various options including serializer options
`Results.Text`	`text/plain` (default)	Produces a text response, with a configurable content type
`Results.File`	`application/octet-stream` (default)	Writes a file to the response, with a configurable content type
`Results.Bytes`	`application/octet-stream` (default)	Writes a byte array to the response, with a configurable content type

In addition to these options, you can return a plain string or a more complex type. For example, your handler can obtain the total cost from the service and simply return that:

```
return bookingService.Calculate(booking);
```

The response will consist of just the value, with a content type set to `text/plain`. Note that you will need to adjust your Fetch code on the client to use the `text()` method instead of the `json()` method, and you will supply the entire response to the interpolated string in the alert:
