next chapter with a look at approaches to minimize errors in your application, how to handle them gracefully when they occur, and how to use logging to understand what is happening once your application is live.

Summary

- Client-side technologies can help you to improve the usability of your application.
- While it is still a great library, the case for using jQuery for manipulating the DOM and making asynchronous (AJAX) requests is diminishing as more and more browsers align behind standards.
- You can use a `PartialResult` for returning blocks of HTML to an AJAX call.
- You must ensure you include a request verification token when posting form values via AJAX to a page handler method.
- The request verification token can be included in the header or within the request body when the request content type is x`-www-form-urlencoded`.
- You must include the token as a header when posting JSON in the request body.
- When posting JSON to a page handler, you must mark the handler parameter with the `FromBody` attribute to tell the framework which binding source to use.
- Request handers are a new feature in .NET 6 and form part of the minimal API.
- Request handlers map routes to functions and can take parameters.
