page includes the exception type, its message, the filename, the line or lines of code where the exception was raised, and its stack trace. It also includes some information about the request, including details about cookies, request headers, the query string, and information about the route that was invoked. You can see this in action by removing the check for null in the `CityModel`'s `OnGetAsync` method and then navigating to the page, passing in a nonexistent city name in the URL. Change the `OnGetAsync` method in City.cshtml.cs to comment out the check for null.

Listing 12.1 Commenting out the null check

```
public async Task<IActionResult> OnGetAsync()
{
    City = await _cityService.GetByNameAsync(Name);
    //if (City == null)          ❶
    //{                          ❶
    //    return NotFound();     ❶
    //}                          ❶
    return Page();
}
```

❶ Comment out the null check.

Rebuild the application, and navigate to /city/mikebrind. The Developer Exception page should appear, informing you that an unhandled exception occurred while processing the request (figure 12.1).
